54 Robot device for loading and unloading spools in wire winding machines.

57 The robot device for the loading of empty spools (Z') and the unloading of filled spools (Z) respectively into and from wire winding machines (B, B', B'') aligned in a single file on one side of a track (A) comprises a carriage (1) which moves along the track and stops at the machine to be served. The carriage (1) carries a vertical supporting structure (23) onto which there are mounted two brackets (51, 51') which can be moved vertically and can be rotated around the supporting structure (23). A slide (17) which moves in a direction transverse to the movement of the carriage (1) serves for introducing one of the brackets (51, 51') into the winding machine, where the bracket is then lifted to receive the filled spool from the winding machine, or to load an empty spool onto the winding machine. On a platform (24) located on top of the supporting structure (23) there are arranged the central power and control unit (25), the distribution unit and the electric and electronic apparatus for controlling the various motion devices of the robot. On the said platform there are also arranged the means (77) for cutting the wire (M) being fed to the filled spool and for holding the leading end of the cut wire, as well as the devices (61-73) for securing the trailing end of the cut wire to the filled spool, and the leading end of the cut wire to the core of the empty spool.

In the apparatuses for the production of wire, it is known to align in a single file a plurality of wire winding machines, which present equal or different operational features, both in relation to the size of the spools and in relation to the section of the wires, in such a manner that said winding machines are arranged on one side of a rectilinear guide, with the winding axis which is arranged parallelly to the longitudinal axis of the mentioned guide, along which there moves a programmable robot which effects the loading of the empty spools and the unloading of the filled spools to and from the winding machines, taking the empty spools and depositing the filled spools from and into feeding and collecting stations which are usually located at one end of the said guide. The invention relates to a novel type of robot for effecting the above mentioned operations, which differs from similar robots of known type, due to a greater reliability, to the fact that it can operate on spools having diameter and weight which can vary within ample limits, to the fact that it presents reduced overall dimensions and to the fact that it presents a greater

0142813

operational flexibility, particularly in the steps of taking of the empty spool and of discharge of the filled spool.

5

The above and other features of the robot according to the invention, and the advantages deriving therefrom, will appear evident from the following description of a preferred embodiment of same, illustrated by way of non-limiting example in the Figures of the attached fifteen sheets of drawings, in which:

10

- Figure 1 shows in perspective view the robot positioned at a winding machine, and prepared to serve this latter;

15

- Figure 2 shows the robot without the upper unit for the taking and the cutting of the wire and without the unit for securing the trailing end and the leading end of the winding, the robot being sectioned along its height and along the length of the underlying carriage;

20

- Figure 3 shows the carriage of the robot, sectioned along line III-III of Figure 2;

25

- Figure 4 shows the carriage of the robot, in plan view from the top;

- Figure 5 shows some constructional details of the robot, taken along line V-V of Figure 2;

30

0142813

- Figure 6 is a plan view from the top of the brackets by means of which the robot supports the spools and shows also the slide which carries said brackets;

5 - Figure 7 is a side view of a discharge mechanism
which can be associated to the bracket of the robot which
will carry the filled spool;

10 - Figure 8 shows further details of the mechanism
according to Figure 7, in a plan view from the top;

15 - Figure 9 shows some details of the upper portion of
the upright structure of the robot, in plan view from the
top;

20 - Figure 10 and 11 are side elevation views of the
devices mounted in the upper portion of the robot, and
serving for the cutting and holding of the wire in the
wire winding machines, and also for the securing of the
trailing end and of the leading end of the winding;

25 - Figure 12 shows constructive details of the unit
of Figure 10 sectioned along line XII-XII;

30 - Figure 13 shows the unit of Figure 11 sectioned along
line XIII-XIII;

 - Figure 14 shows frontally and with parts in section
the devices which cut the wire in the wire winding machines,
and which simultaneously hold the new leading end of the

0142813

wire itself;

5 - Figure 15, 16, 17, 18 and 19 show in perspective view the parts of interest of the robot during as many working steps.

10 Referring firstly to Figure 1, reference letters B, B', B" indicate wire winding machines of non-automatic type, which may present identical or even different operational features, arranged on one side of the rectilinear track A upon which is shiftable, in a controlled manner, the robot according to the invention which
15 automatically operates on the wire winding machine which must be unloaded of the filled spool and consequently must be loaded with a new empty spool. The spools are arranged with their winding axis parallel to the longitudinal axis of the track A. The devices which provide for the loading
20 of the robot with the empty spools having the required size, and the devices which discharge or receive from the said robot the filled spool cyclically unloaded from a wire winding machine, are usually arranged at one of the ends of the track A, in a manner which can be easily conceived and
25 put into practice by persons skilled in the art, on the basis of the operational features of the robot which will appear from the following description.

30 From Figures 1, 2, 3 and 4 it can be noted that the robot comprises a carriage 1 provided with wheels 2

0142813

(of which some are flanged wheels) which carriage 1 moves on the track A, one pair of said wheels being connected by a shaft 3 provided with a flexible coupling 4 and which, through a positive drive consisting of a toothed belt 5 and of toothed pulleys 6-6', is driven by a hydraulic motor 7 secured frontally on the carriage 1 by means of a bracket 8. In consideration of the fact that during the operation of the robot, the carriage 1 is loaded in such a manner as to be urged to swing upwardly by being fulcrumed on the rail which is next to the row of winding machines, this swinging motion is prevented by the fact that rollers 9 which are mounted freely rotatable on the carriage 1 cooperate with the outer flank of the other rail of the track A. In Figure 4, reference numeral 10 indicates a vertical axis latch member which is mounted on one front of carriage 1 and is driven by a hydraulic jack 11, said latch member presenting a bottom end shaped like a frustum of cone. Whenever the robot is located at the stations which provide for the loading and unloading onto and from the said robot, respectively of an empty spool and of a filled spool, the latch member 10 is lowered and cooperates with a conical seat (not shown) secured on the ground or to the flank of a rail of track A, the whole in such a manner that the various operational units located on carriage 1 come to be correctly positioned with respect to the said loading or unloading stations. Whenever the robot is called to serve a winding machine, automatically the latch member 10 is lifted, and motor 10 is actuated so as to move the carriage 1 on track A with accelerated motion, and thus transfer said carriage quickly

0142813

quickly to the winding machine which is to be served.
Prior to reaching said winding machine, which in Figure 1
we suppose to be the one denoted by reference letter B",
the carriage 1 cooperates with a fixed sensor (not shown)
5 which promotes the slowing down of motor 7 so that the
carriage approaches slowly the winding machine B" which is
about to terminate or has terminated the winding operation
and which has opened its hood in such a manner as to give
access to the filled spool Z which is located in said winding
10 machine. When the carriage 1 reaches a sensor 13 fixed on
the ground (Figure 4), said sensor 13 detects the first
one of a pair of reference members 12, 12' secured to the
carriage 1, and controls the stopping of motor 7 and
subsequently the lowering of latch member 10 which enters
15 a fixed slot-shaped seat 14, arranged parallel to track A
and presenting a predetermined length. Subsequently the
motor 7 is again actuated in order to move slowly the
carriage 1 in the opposite direction, until the sensor 13
detects the reference member 12, while the latch member 10
20 abuts against the end 114 of the said slot 14. The robot
is thus correctly positioned with respect to the wire
winding machine B".

On carriage 1 there are secured, at right angles with
25 respect to track A, a pair of rectilinear, parallel and
horizontal guides 15, 15' presenting an inverted "L" or a
"T" section, and onto which there is slidably mounted a
slide 17 (see also Figure 6) by means of sliding shoes 16
which cooperate with said guides on their upper, side and
30 bottom surfaces, said slide 17 being in its rest position

0142813

where indicated with full lines in Figure 3 and being movable to the position indicated with dash lines in the same Figure 3. In order to move in alternate directions the slide 17 there is provided a piston and cylinder assembly 18 (Figure 3) secured by its cylinder to the carriage 1, parallel to the guides 15, 15', and carrying with its piston end a fork 19 onto which there is rotatably mounted a pinion 20 cooperating with a pair of superposed racks 21, 22 which are parallel to each other and are also parallel to the said guides 15, 15', one of said racks (21) being fixed to the carriage 1, while the other rack 22 is fixed to the slide 17. By this arrangement the slide 17 can be moved along a path which is double the running path of the pinion 19 with all consequent advantages. On the end portion of the slide 17 which faces the wire winding machines there is obtained an opening inside which there is inserted by one of its ends and there is flange-mounted a tubular column 23 vertically arranged and onto the upper end of which there is secured the orizontal platform 24. On said platform there is mounted the hydraulic power and control unit 25 (Figure 1) and there are also mounted the electrovalves and the electrical and electronic apparatuses which are required for the programmed operation of the various motion devices carried by the robot. From the above mentioned control apparatuses there departs a bundle of pipes (not shown in Figure 2) which pass axially through column 23 in downward direction and are connected the end 126, secured to slide 17, of a bundl of flexible pipes associated to a guide catenary 26 (Figur 4)

0142813

which by its other end 226 is secured to carriage 1 and serves for the power feeding of the piston and cylinder assembly 18, the hydraulic motor 7 and the hydraulic jack 11 of the latch member 10. On the column 23 there is rotatably mounted (Figure 2) with the interposition of radial bearings 27, 27' and of at least one axial bearing 28, a jacket 29 on the upper end of which there is secured a collar 30 which is located at a short distance from platform 24. A crown gear 31 is secured to collar 30, coaxially to the assembly 23, 29, said crown gear cooperating with a pinion 32 keyed on the shaft of a small hydraulic motor 33 which is fixedly mounted on platform 24, on said platform 24 there being also mounted a hydraulic jack 34 which actuates a conical and vertical latch member 35 adapted to cooperate with one of four conical seats 36 arranged angularly equispaced on said collar 30, the whole in such a manner as to guarantee a stable positioning to the mentioned components 29, 30 in the angular position into which they are sequentially brought by motor 33 (see after). The engagement or rest condition of the latch member 35 is sensed by proximity switches 37, 37' which sense the position of an appendix 38 laterally fixed to 35, while the angular position of the assembly 29, 30 is sensed by a proximity switch 39 (Figure 9) carried by platform 24 and arranged along the rotational orbit of an appendix 40 laterally secured to collar 30. Similar devices are provided in order to detect the condition of the latch member 10 mounted on carriage 1. The driving of units 33 and 34 can be easily effected by the hydraulic control box and by the

0142813

distribution units mounted on platform 24.

On jacket 29 (Figure 2) there is mounted in axially shiftable but non-rotatable manner (thanks to the key and groove arrangement 43, 44) a sleeve 42 provided at its inner ends with bushings 41 made of material presenting a low friction coefficient. By making reference also to Figures 5 and 6 it can be noted that on the lower section of sleeve 42 there is secured the central portion of a horizontal and rectangular plate 45. To the side portions of said plate 45 which project laterally of said sleeve there are secured, in symmetric arrangement, the stems of a pair of double-acting hydraulic jacks 46-46' which are vertically directed and are secured by their cylinder bodies to the collar 30. These jacks provide for the axial movement, along jacket 29, of the sleeve 42 and of the parts associated thereto. With reference to Figures 2 and 9 it can be noted that the hydraulic jacks 46-46' are connected to the hydraulic control unit and distribution units arranged on platform 24 by means of ducts 47-47' obtained longitudinally in column 23 and opening into annular recesses 48-48' at different heights on the inner side surface of collar 30. Ducts 49-49' depart from said recesses for the feeding and discharge of the above mentioned jacks, while annular packings 50 provide for the tight sealing of said circuits. The horizontal plate 45 is fixed by its ends to the parallel sides of two identical brackets 51-51' cantilevered in opposite arrangement to the lower portion of sleeve 42, and which present longitudinally the profile shown in

0142813

Figure 2, with a shallow concave supporting bottom, and with side edges 151-151', designed in such a manner that each bracket (51-51') can safely support and carry a spool Z. A further strengthening plate 45' is secured to the upper portion of sleeve 42 and to the top portions of the sides of the two brackets 51-51' so as to structurally strengthen and stiffen the whole assembly. When the robot reaches the wire winding machine B" to be served, the brackets 51-51' are directed at right angles with respect to the track A and the bracket 51' which is not facing the winding machine carries an empty spool Z' which has been loaded from the loading station at one end of track A. The brackets 51-51' are in their lowered position (the stems of the jacks 46-46' are fully expanded) and the slid 17 is in its rest position, as indicated in full lines in Figure 3. When the carriage 1 has been correctly positioned with respect to the wire winding machine B" and the said winding machine has completed its working cycle (and the protective hood has been opened, as shown in Figure 1) the slide 17 is moved towards the said winding machine so as to position the bracket 51 below the filled spool Z, without interfering with said spool. At this moment (Figure 15), there takes place the intervention of suitable means (which will be described after) which in correct time relationship effect the cutting of the wire which is directed to the filled spool Z, hold the leading end of said wire and secure the trailing end of the wound wire onto the winding or coil, by applying on this latter a piece of adhesive tape. Subsequently, the brackets 51-51' are lifted, as shown in Figure 16, so that the bracket 51

0142813

comes at a short distance from the spool Z, arranged with its side edges 151 laterally and at the exterior of the flanges of spool Z. For this purpose there are provided sensor means which are capable of sensing the position of the bracket 51 with respect to the flanges of the spool Z. In correct time relationship the filled spool Z is freed from the center or tailstock P. Subsequently, the robot moves on track A in the direction indicated by arrow F in Figure 15, for a short run having a length which is equal to length of the slot 14 (see Figure 4) the whole in such a manner that thanks to the engagement of the side edges 151 of bracket 51 with the flanges of the filled spool Z, this latter is extracted from the center or tailstock of the winding machine. At this point, the slide 17 is moved away from the winding machine B" and is brought into the cycle starting position, in such a manner that the bracket 51 loaded with the filled spool Z is brought clear off the hood of the winding machine B". Thereafter, as shown in Figure 17, the latch member 35 (Figure 2) is lifted and motor 33 is actuated so that the brackets 51-51' are rotated of 180° around column 23, thus inverting their respective positions. The motor 33 is then stopped and the latch member 35 goes back to its locking position. The slide is now again moved near to the winding machine B" so that the bracket 51' positions the empty spool Z' between the center and the tailstock of said winding machine (Figure 18). Thereafter the robot moves on track A in the same direction of movement of the tailstock of the winding machine B" so as to promote the taking up of the spool Z' by the centering and driving means of the said winding machine, and subsequently the

0142813

5 bracket assembly 51-51' is lowered. At this point, there
takes place the intervention of the devices mounted on
platform 24 (and which will be described later) which
secure the leading end of the wire to be wound, on the
10 core of the empty spool Z'. Subsequently the latch member
10 (Figure 4) is lifted and the motor 7 is actuated. The
robot (see Figure 19) moves away from the winding machine
which has been served and returns to the extremity of
track A where the filled spool Z extracted from B" will be
10 unloaded and the bracket 51' will be loaded with another
empty spool. From Figure 1 it can be noted that above and
parallelly to track A there is arranged a guide 52 which
by means of movable trolleys H supports the bundle of
cables K serving for the feeding and the automatic and
15 programmed operation of the robot.

For the unloading of the filled spool from the bracket
51 of the robot there can be provided means located at the
station where the spool is unloaded, or means which are
20 associated to the said bracket as shown in Figures 7 and 8.
These means comprise a pusher plate 53 covering the inclined
upper bottom portion of the bracket 51, to which the said
pusher plate 53 is transversally fulcrumed at 54. A pair
of double-acting jacks 55-55' secured by their cylinder
25 bodies to the side edges 151 of the brackets 51-51' and
connected by their stems to lugs 56-56' on the lower side
of the pusher plate 53, promote, upon suitable control, the
lifting of said pusher plate 53 as shown in dash lines in
Figure 7, so as to cause the pushing of the filled spool Z
30 which is thus discharged from the bracket 51.

0142813

With reference to Figures 10 to 14 there is now described the construction and operation of the unit mounted on platform 24 and which provides for: the cutting of the wire fed from the wire winding machines; the holding of
5 the new leading end of said wire; the securing of the trailing end of the wire which has been wound onto the same winding; and lastly the securing of the new leading end of the wire to the core of the empty spool which has been inserted into the winding machine. This unit, which
10 faces the file of wire winding machines, comprises a vertical guide 57 fixed to platform 24 and onto which there is movable vertically a slide 58 which on its turn acts as a guide for another vertical slide 59. The hydraulic jacks 60 and 60' promote the movement of the slides 58 and 59.
15 In the lower portion of the slide 59 there is mounted a head member 61 which carries a freely rotatable roller 62, which is lined with elastic yielding material and is arranged with its axis parallel to the longitudinal axis of track A. To the guide 57 there is secured, in overhanging
20 position, a supporting member 63 which supports in a rotatable manner a bobbin 64 of adhesive tape, which tape is led over rollers 65-65' and lastly over said roller 62, onto which it is kept by a small parallel counter-roller 66 made of metal and presenting annular grooves so as to
25 have a reduced contact surface with the adhesive side of the tape web 64'. The counter-roller 66 is rotatably supported at its ends by arcuate supports 67 (see Figure 11) which are fulcrumed at 68 to the head member 61 and are interconnected by a transverse bar 69 onto which there
30 acts an adjustable pressure member 70, thus ensuring the

0142813

required cooperation of counter-roller 66 with roller 62.

Parallel to roller 62 and above same, there is
interfulcrumed at 71 an arcuate lever 72 carrying at its
end cutting means 73 while its other end is connected to
5 a jack 74 secured to slide 59. Thanks to said jack, the
above mentioned cutting means can be brought from the rest
position indicated in Figure 10 with full lines, to the
cutting position indicated with dash lines, and viceversa.
Laterally with respect to head member 61, parallel to
10 roller 62 there is fulcrumed at 75 a lever 76 which viewed
frontally (Figures 12, 13) presents an "L" shape so as to
result with its bottom leg parallelly arranged with respect
to the axis of the said roller 62 and so as to be able to
rotate around said roller. On the bottom leg portion of
15 said lever 76 there are mounted the cutting means 77
(which will be described later) for the cutting of the wire
fed to the winding machines and which hold the new leading
end of the wire itself. Lever 76, as it can be seen from
Figure 11, is connected to a jack 78 which is capable of
20 bringing same from its rest position (Figure 10) indicated
with full lines, to the position indicated with dash lines,
and viceversa. With reference to Figures 10 and 15 it can be
noted that when the robot bracket 51 is introduced into
winding machine B" for extracting the spool Z, the
25 assembly composed of the slides 58-59 is lowered in such a
manner that the roller 62 comes into contact with the
trailing end of the wire M which has been wound on the said
spool, which latter has been held and cut by the holding
and cutting means 77. The trailing end of the wire which
30 has been wound on spool Z results in this manner to be

0142813

blocked on the same winding by the pressure of roller 62.
At this point there is imparted the control for the rotation
of the winding machine in the direction indicated in
Figure 15 by arrow F1, so that a portion of adhesive tape
5 64' is applied onto the winding of spool Z to block the
trailing end of the wire which has been wound. In this
phase, the spool Z may be caused to rotate even for more
than one full turn. Alternately, the holding and cutting
means 77 can be operated after the applying of the adhesive
10 tape binding. When, later, the spool Z has been stopped, the
assembly comprising the slides 58-59 is lifted, and the
cutting means 73 are actuated which separate the
adhesive binding applied on the wire winding from the
continuous web 64'. The new leading end of wire M is
15 always held by the means 77. In the subsequent step
illustrated in Figure 18, when the robot has inserted the
empty spool Z' into the winding machine, the leading end
of the wire M is anchored to the core of the empty spool
in the following manner. The lever 76 which carries the
20 means 77 is brought into the position indicated in Figure
10 with dash lines, so that the wire M held by the said
means 77 is passed below the roller 62. In this manner,
when the assembly of slides 58-59 is lowered, the wire M
is pressed onto the core of spool Z' by roller 62 and the
25 leading end of adhesive tape 64'. The means 77 are set at
rest position, and the spool Z' is rotated in the direction
indicated in Figure 18 by arrow F1, so that a length of
adhesive tape 64' is applied on the core of said spool Z'
so as to secure onto it the leading end of wire M. Also
30 during this step the spool Z' may be rotated for one turn

0142813

or more. When the spool Z' has been stopped, the assembly of slides 58-59 is lifted, and the cutting means 73 (Figure 10) are actuated in order to separate the continuous web 64' from the binding applied onto the core of spool Z'; thereafter, the means 73 and 77 are again brought to their cycle starting position. Means 77 are illustrated in Figure 14 and comprise a fork 78 secured to lever 76 and having a leading-in V-shape, so as to lead the wire M between the jaws 79-79' of a clamping device. Of said jaws, the one indicated by reference numeral 79 is fixedly secured to lever 76, while the other jaw 79' is mounted, with the interposition of an elastic assembly 80, on a lever 81 which is fulcrumed at 82 to lever 76 and is connected to a driving jack 83 secured to the said lever 76. On lever 81, rearwardly with respect to the clamping surface of jaw 79', there is secured a cutting blade 84, while an end of the other jaw 79 is used as counterblade. In Figure 14 means 77 are illustrated in their rest position. It can be easily understood how, by retracting the jack 83, the jaw 79' closes on jaw 79 thus clamping the wire M, and the prosecution of the closing motion of jaw 79', consented by the elastic assembly 80, promotes the cutting of the same wire by the blade 84.

25

30

CLAIMS

1. A robot device for the loading of empty spools
(Z') and the unloading of filled spools (Z) respectively
5 into and from wire winding machines (B, B', B'') aligned
in a single file on one side of a path (A), comprising
a transport carriage (1) movable along said path (A) and
carrying a vertical supporting structure (23) onto which
there are movably mounted at least two brackets (51, 51')
10 for supporting the empty and filled spools (Z', Z), said
brackets (51, 51') being arranged in opposite directions,
lifting and lowering devices (46, 46') and rotating devices
(31, 32, 33) being provided to promote the vertical movement
and the rotation of the brackets (51, 51') around the
15 said vertical supporting structure (23), characterized
by the fact that the winding axes of the wire winding
machines (B, B', B'') and consequently the axes of the
spools housed in the said wire winding machines, are
substantially parallel to the longitudinal axis of the
20 said path (A) along which moves the said carriage (1) at
least in the section of said path (A) facing the wire
winding machine arranged at its side, and that transverse
displacement means (17) are provided on the carriage (1)
for moving the said vertical supporting structure (23) in
25 a direction which is substantially perpendicular to the
longitudinal axis of the said path (A) and to the winding
axis of the spool (Z) housed in a winding machine (B)
whereby the unloading of the filled spool (Z) from the
winding machine onto a bracket (51) and the loading of the
30 mpty spool (Z') from a bracket into the winding machine

0142813

are effected by moving the said spools (Z, Z') in directions which are perpendicular to the said winding axes of the said spools.

5 2. A robot device according to claim 1, characterized by the fact that the transverse displacement means (17) consist of a horizontal slide movable on the carriage (1) in a rectilinear direction transversely to the direction of movement of the said carriage along the said path (A).

10 3. A robot device according to claim 1, characterized by the fact that the said brackets (51, 51') are cantilevered with respect to the vertical supporting structure (23).

15 4. A robot device according to claim 1, characterized by the fact that each bracket (51, 51') presents, on its longitudinal sides which are perpendicular to the winding axes of the spools (Z, Z'), side engagement members (151, 20 151') adapted to engage at least one of the flanges of a spool, said engagement taking place upon controlled movement along said path (A) of the carriage (1) when the brackets are in their lifted position and introduced in the wire winding machine, whereby the controlled movement 25 of the carriage (1) in one direction causes the freeing of the filled spool (Z) from the center or tailstock (P) of the wire winding machine for the unloading of the filled spool onto the bracket, while the controlled movement of the carriage (1) in the opposite direction causes the 30 engagement of the empty spool (Z') with the center or

0142813

tailstock (P) of the wire winding machine for the loading of the empty spool on the said winding machine.

5. A robot device according to claim 4, characterized by the fact that the controlled movement of the carriage (1) in both directions is delimited by the insertion of a movable member (10) mounted on the carriage (1) into a fixed slot-shaped seat (14) arranged on the path (A) of the carriage, whereby the movement of the carriage in both directions is determined by the length of said slot-shaped seat.

6. A robot device according to claim 1, characterized by the fact that on the transport carriage (1) there are further arranged:

- a) means (77) for cutting the wire (M) fed from the wire winding machine to the filled spool (Z) and for holding the leading end of the said wire which has been cut;
- b) means (61-73) for securing the trailing end of the wire which has been cut onto the wire winding formed on the filled spool (Z) and for securing the said leading end of the wire to the core of the empty spool (Z') which has been subsequently inserted into the winding machine.

7. A robot device according to claim 6, characterized by the fact that the said means (77) for cutting and holding

the wire and the said means (61-73) for securing the wire are mounted on a platform (24) arranged at the top of the vertical supporting structure (23) carried by the carriage (1), means (58-60) being provided for moving the
5 said cutting and holding means and the said securing means into and out of their operative range, all of the said means being hydraulically powered and controlled by a hydraulic power and control unit (25) located on the said platform (24).

10

8. A robot device according to claim 1, characterized by the fact that on the transport carriage there are arranged:

15

a) a hydraulic motor (7) for moving the said carriage (1) along the said path (A);

b) a hydraulically powered unit (46, 46') for the vertical movement of the brackets (51, 51');

20

c) a hydraulically powered unit (33) for the rotational movement of the brackets (51, 51');

25

d) a hydraulically powered unit (18) for the transverse displacement means (17);

e) a hydraulic power and control unit (25) for the controlled feeding of all the above mentioned hydraulic motors and hydraulically power d units.

9. A robot device according to claim 8, characterized by the fact that the said hydraulic power and control unit (25) is located on a platform (24) arranged at the top of the vertical supporting structure (23) carried by the carriage (1), on said platform (24) there being also mounted all the electrical and electronical apparatuses controlling the various operational movements of the robot.

10. A robot device according to claim 8, characterized by the fact that it further comprises, mounted on each bracket (51, 51'), a pusher plate (53) for the discharge of the filled spool (Z) which has been loaded onto the bracket from the winding machine, said pusher plate being hydraulically powered and being controlled by the said hydraulic power and control unit (25).

11. A robot device according to claim 1, characterized by the fact that each bracket (51, 51') is constructed so as to present a substantially horizontal surface for supporting the spools (Z, Z'), said horizontal surface presenting a concavity or shallow recessed portion arranged transversally to the length of the bracket, for the stable positioning of the spool carried by the said bracket.

12. A robot device according to claim 7, characterized by the fact that the means for moving the wire cutting and holding means (77) and the wire securing means (61-73) into and out of their operative range comprise a vertical guide

0142813

(57) fixed to platform (24) onto which guide there is slidably mounted at least one slide (58, 59) carrying at its lower end the said wire cutting and holding means (77) and the said wire securing means (61-73).

5

13) A robot device according to claim 12, in which the wire cutting and holding means (77) comprise a lever (76) fulcrumed at the lower head end of said slide (59) and provided at its free end with a clamping device formed by a pair of jaws (79, 79'), one of said clamping jaws carrying also a blade (84) while the other one acts as a counterblade.

10

14) A robot device according to claim 13, in which the wire securing means comprise a roller (62) onto which there is passed a web of adhesive tape (64') supplied from a suitably arranged supply bobbin (64), and a blade (73) for cutting the adhesive tape (64') mounted on a lever (72) fulcrumed at the lower head end of said slide (59), whereby when a filled spool (Z) must be unloaded from the wire winding machine, the wire cutting means (77) cut the wire (M) being fed to the spool and hold the leading end of the wire which has been cut, while the wire securing means (61-73) apply a suitable length of adhesive tape (64') to block the trailing end of the wire on the winding formed on the filled spool by suitably pressing the roller 62 on the said winding, the adhesive web being subsequently cut by the said blade (73), and when an empty spool (Z') is inserted in the wire winding machine, the lever (76) carrying the leading end of the wire is swung so as to bring the wire in contact with

20

25

the roller (62) carrying the adhesive tape (64'), the said roller (62) being subsequently pressed onto the core of the empty spool (Z') which is then rotated, so as to apply a suitable length of adhesive tape with the wire interposed and to secure the leading end of the wire on the core of the empty spool.
